SYNTHESIS AND STRUCTURE OF 3,4,5-TRIHYDROXY-5-(4-NITROPHENYL)IMIDAZOLIDIN-2-ONE

Keywords: 4-nitrophenylglyoxal, N-hydroxyurea, 2-methylfuran, 5-aryl-3,4,5-trihydroxyimidazolidin-2-ones; structure, α-benzoins.

4-Nitrophenylglyoxal reacts with N-hydroxyurea both in water and in acetic acid forming the mixture of diastereomers of 3,4,5-trihydroxy-5-(4-nitrophenyl)imidazolidin-2-one. The diastereomer with cis-orientation of OH-groups dominates. In the acetic acid medium, 4-nitrophenylglyoxal reacts with 2-methylfuran selectively yielding 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone.

INTRODUCTION

Arylglyoxals are important precursors in the forming of some heterocyclic compounds,[a-1,4] but the investigation of such interesting chemical properties of arylglyoxals, as their interaction with N-hydroxyurea[a] and with activated furans,[5] has just recently begun and needs to be continued.

Interaction of arylglyoxals with N-hydroxyurea in aqueous medium occurs in three stages and involves the formation of acyclic N-hydroxyureas (1) at the first stage, 5-aryl-3,4,5-trihydroximidazolidin-2-ones (2 and 3) at the second stage and 5-aryl-3-hydroxymimidazolin-2,4-diones (5-aryl-3-hydroxyhydantoins) (4) at the third stage[5] (Scheme 1).

Scheme 1. Arylglyoxal’s interaction with N-hydroxyurea in aqueous medium

In this case, the product's identity depends on arylglyoxal’s nature. 4-Tolyglyoxal and 4-anisylglyoxal form acyclic ureas 1c, 1d, and 5-aryl-3-hydroxyhydantoins 4c, 4d.[5] Phenylglyoxal usually gives 3-hydroxy-5-phenylhydantoin 4a, but if this reaction occurs at 10-20°C without further heating, the mixture of 3,4,5-trihydroxy-5-phenylimidazolidinelines (2a and 3a) and 3-hydroxy-5-phenylhydantoin (4a) is formed. Interaction of 4-chlorophenylglyoxal with N-hydroxyurea at the room temperature selectively yields the main diastereomer of 5-(4-chlorophenyl)-3,4,5-trihydroximidazolidin-2-one (2b) with the cis orientation of hydroxyl groups at C-4,5 carbon atoms.[5,7] Careful heating of the reaction mixture leads to the receiving of 5-(4-chlorophenyl)-3-hydroxyhydantoin (4b).

5-Aryl-3,4,5-trihydroximidazolidin-2-ones (2a, 3a, 2b, 3b) are easily converted into 5-aryl-3-hydroxyhydantoins (4a and 4b) under heating in water, acetonitrile or dichloromethane.

The interaction in the acetic acid medium during one day (as described in the referenced procedure[5]) of such arylglyoxals as phenyl-, 4-bromophenyl-, 4-chlorophenyl-, 4-fluorophenyl-, 4-methoxyphenyl- and 4-methylglyoxal with N-hydroxyurea gets 5-aryl-3-hydroxyhydantoins 4a-f (Scheme 2) selectively.

Scheme 2. Synthesis of 5-aryl-3-hydroxyhydantoins 4a-f in acetic acid medium

But the interaction of 4-nitrophenylglyoxal with N-hydroxyurea has not been investigated yet.

As it is known, arylglyoxals interaction with furan derivatives at the room temperature can proceed in two ways, which are a little bit different. Phenylglyoxal and 4-X-phenylglyoxals (X= F, Cl, Br) react with 2-methylfuran yielding only α-benzoins (5a-d) (Scheme 3).[6,8] Similarly, phenylglyoxal and 4-fluorophenylglyoxal reacts with N,N-dimethylhydrazone of furan-2-carbaldehyde yielding α-benzoins (6a,d).[6,8] But it has been shown, that at
the room temperature 4-chlorophenylglyoxal and 4-bromophenylglyoxal forms β-benzoens (7b,c)\(^5,6\) via primary formation α-benzoens (6b,c). α-Benzoens(6d) spontaneously isomerizes into β-benzoens (7d) at the room temperature during one month.\(^8\)

Scheme 3. Synthesis of benzoens 5a-d, 6a-d, 7b-d .\(^6,8\)

4-Nitrophenylglyoxal’s interaction with both 2-methylfuran and N-hydroxyurea has remained not investigated. This arylglyoxal has a high activity due to the presence of 4-NO\(_2\) moiety, a strong electronegative substituent. It might cause a different course of the described reaction.

As it was shown before, arylglyoxals’ interaction with N-hydroxyurea\(^2\) and furans\(^6,8-10\) have some differences which depend on the nature of the substituting group in arylglyoxal. But it wasn’t clear at all what products would be received if arylglyoxal had a strong electronegative substituting group, such as, for example, nitro group. That’s why we decided to fill in this gap.

So, the first goal of our present research was to investigate both the interaction of 4-nitrophenylglyoxal with N-hydroxyurea in aqueous medium and acetic acid medium. The second goal was to investigate the interaction of 4-nitrophenylglyoxal with 2-methylfuran in the same mediums.

**EXPERIMENTAL**

\(^1\)H NMR spectra were recorded on a Varian VXP-300 spectrometer and Varian Jemini 400 spectrometer (300 and 400 MHz, respectively). \(^13\)C NMR spectra were recorded on a Varian VXP-300 spectrometer (75 MHz). The solvents were DMSO-d\(_6\) (compounds 2g, 3g, 5e) and CDCl\(_3\) (compound 5e).\(^1\)H NMR chemical shifts were reported relative to the residual solvent protons as an internal standard (in CDCl\(_3\)). Solvent carbon atoms served as an internal standard for \(^13\)C NMR spectra (in CDCl\(_3\)) ppm (CDCl\(_3\)): 77.16 ppm). Mass spectra were recorded on a VG 70-70EQ mass spectrometer in fast atom bombardment (FAB) mode (FAB). The solvents were purified and dried according to the standard procedures.

N-Hydroxyurea\(^11\) was obtained according to published procedures.

4-Nitrophenylglyoxal hydrate was obtained according to the standard procedure by 4-nitroacetophenone oxidation by H\(_2\)SeO\(_3\) in boiling AcOH for 2h, the removing of AcOH and the crystallization of the residue from boiling water, as a yellow powder, mp 87–89°C. \(^1\)H NMR (400 MHz, DMSO-d\(_6\)): \(\delta = 5.66\) (1H, t, \(J = 6.8\) Hz, CH(OH)2); 7.03 (2H, d, \(J = 6.8\) Hz, CH(OH)2); 8.29 (2H, d, \(J = 9.2\) Hz, H Ar); 8.34 (2H, d, \(J = 9.2\) Hz, H Ar).

Preparation of cis- and trans-3,4,5-trihydroxy-5-(4-nitrophenyl)imidazolidin-2-ones 2g, 3g in aqueous medium.

4-Nitrophenylglyoxal hydrate (217 mg, 1.101 mmol) was dissolved in boiling water (10 mL), after cooling to 14°C a solution of N-hydroxyurea (93 mg, 1.223 mmol) in water (5 mL) was added at stirring. The reaction solution was maintained at 14°C for 25h, then the obtained precipitate was filtered off, washed out with cold water (2 mL), dried at 14°C under vacuum (3 mmHg), yielding 114 mg (38%) cis-diastereomer (4S,5S)-3,4,5-trihydroxy-5-(4-nitrophenyl)-imidazolidin-2-one hydrate (2g, purity 79%) as yellow crystals, m.p. 132–133 °C. \(^1\)H NMR (300 MHz, DMSO-d\(_6\)): \(\delta = 4.55\) (1H, d, \(J = 7.5\) Hz, CH(OH)2); 6.49 (1H, s, OH); 6.63 (1H, d, \(J = 7.5\) Hz, CH(OH)2); 7.75 (2H, d, \(J = 8.7\) Hz, C(2H)2, C(6)H Ar); 8.24 (1H, s, NH); 8.26 (2H, d, \(J = 8.7\) Hz, C(3H), C(5)H Ar); 9.13 (1H, s, NOH). \(^13\)C NMR (75 MHz, DMSO-d\(_6\)): \(\delta = 82.6\) (C-4 imidazolidine); 89.4 (C-5 imidazolidine); 123.4, 127.6 (C-2, C-6, C-3, C-5 Ar); 147.3 (C-1 Ar); 149.9 (C-4 Ar (C–NO2)); 159.5 (C=O). \(^1\)C NMR (75 MHz, APT mode, DMSO-d\(_6\)): \(\delta = \text{a: CH:} 82.6\) (C-4 (CH(OH) imidazolidine)); 123.4 (C-2, C-6, Ar); 127.6 (C-3, C-5 Ar); b) Cq, C=O: 89.4 (C-5 imidazolidine); 147.2 (C-1 Ar); 149.8 (C-4 Ar (C–NO2)); 159.5 (C=O). MS (FAB), m/z 256 [M+H]+ (77); 210 (13); 195 (18); 106 (87); 88 (100). Anal. Calc. for C\(_{16}\)H\(_{17}\)O\(_{2}\)N\(_3\): C 39.52; H 4.25; N 15.26. Found: C 39.52; H 4.25; N 15.26.

The filtrate was concentrated under vacuum (2 mmHg) at 16°C to the volume of 7 mL, the obtained precipitate was filtered off, dried under vacuum (2 mmHg), resulting 93 mg (31%) mixture diastereomers 2g and 3g in molar ratio 59:41 (1H NMR).

The second filtrate was concentrated under vacuum (2 mmHg) at 16°C to volume 2.5 mL, the obtained precipitate was filtered off, dried under vacuum (2 mmHg), giving 40 mg (13%) mixture diastereomers 2g and 3g in molar ratio 59:41 (1H NMR).

Crystals of the compound 2g were grown from aqueous solution during the reaction. The studied crystal was monoclinic, C\(_{2}\)H\(_{17}\)O\(_{2}\)N\(_3\), at 20 °C, \(a = 11.983(5)\) Å, \(b = 6.988(4)\), \(c = 13.156(7)\) Å, \(\beta = 90.91(4)^{\circ}\), \(V = 1101.6(10)\) Å\(^3\), \(M_r = 273.21\), \(Z = 4\), space group P2\(_1\)/c, \(d_{\text{calc}} = 1.647\) gcm\(^{-3}\), \(\mu = (\text{MoK}α)=0.144\) mm\(^{-1}\), \(F(000) = 568\). X-ray structural study of compound 2g was performed on an Xcalibur 3 automatic four-circle diffractometer (MoKα-radiation, graphite monochromator, Sapphire-3 CCD detector, \(\omega\)-scanning, \(2\theta_{\text{max}} = 50^\circ\)). The structure was solved by the conjugate
Preparation of cis- and trans-3,4,5-trihydroxy-5-(4-nitropheno)-imidazolidin-2-ones (2g, 3g) in acetic acid medium.

N-Hydroxyurea (139 mg, 1.828 mmol) was dissolved at stirring in a solution of 4-nitrophenylglyoxal hydrate (108 mg, 0.548 mmol) in AcOH (3 mL), the reaction solution was maintained at 17°C for 25h, then AcOH was removed by evaporation under vacuum (2 mmHg). The residue was washed with cold (4ºC) water (3 mL). The aqueous extract was evaporated under vacuum (2 mmHg) at 12ºC, the residue was maintained at 17ºC for 25h, then AcOH was removed by evaporation under vacuum (2 mmHg) at 12ºC. Yield 144 mg (96%) mixture of diastereomers 2g and 3g in molar ratio 74:26 (1H NMR).

RESULTS AND DISCUSSION

We have found that 4-nitrophenylglyoxal reacts with N-hydroxyurea in aqueous solution at 14°C yielding mixture of diastereomers of 3,4,5-trihydroxy-5-(4-nitropheno)-imidazolidin-2-one (2g and 3g) (the overall yield of both compounds is 82%) (Scheme 4).

Initially, from the reaction solution crystals of almost pure cis diastereomer (2g) precipitate (according to 1H NMR data molar ratio 2g:3g is 97:3). The same phenomenon was established earlier for 5-(4-chlorophenyl)-3,4,5-trihydroxyimidazolidin-2-one (2b).5,7 Additionally step-by-step evaporation of the aqueous filtrate without any heating gave two portions of the mixture of 2g and 3g. In this mixture, cis diastereomer 2g was dominated (molar ration 61:39 and 59:41, respectively). The overall yield of compound 2g was 63%, the overall yield of compound 3g was 19%.

In the compound 2g the cis orientations of 4-HO- and 5-HO-moieties were confirmed by X-ray structural analysis (Figure 1), earlier in the compound 2b.5

In the crystals, the compound 2g exists as a monohydrate. The five-membered ring adopts an envelope conformation. The C(2) atom lies -0.40 Å off the plane of remaining ring atoms. The N(1) nitrogen atom has a pyramidal configuration. The sum of bond angles centered at the N(1) atom is 360º. The lengths of the N(1)-C(1) bond (1.382(11) Å) and N(2)-C(1) bond (1.355(10) Å) are similar to the corresponding bonds’ lengths in 5-(4-chlorophenyl)-3,4,5-trihydroxyimidazolidin-2-one (2b).5,7 In the compound 2b the substantial difference of those bonds was established [1.3822(16) Å and 1.3462(16) Å].5

DOI: 10.17628/ecb.2019.8.110-114
The C(1)=O(4) group is elongated to 1.251(9) Å as compared to the mean value of 1.210 Å. Similar elongation of this group has been found in the compound 2b [1.2300(15) Å] in N-methoxycarbonyl [1.244(2) Å].

In the compound 2g the ordinary bonds O(2)–C(2) and O(3)–C(3) are somewhat different: the O(3)–C(3) bond [1.409(8) Å] is longer than the O(2)–C(2) bond [1.384(9) Å]. In the compound 2b that bonds difference is some greater [1.409(8) Å and 1.384(9) Å]. The length of the O(1)–N(1) of the compound 2g [1.398(7) Å] is similar to the same bond’s length in 5-(4-chlorophenyl)-3,4,5-trihydroxymimidazolin-2-one [1.4047(14) Å].

In the compound 2g HO-moiety at C(3) atom (5-HO-moiety of hydantoin’s cycle) has the axial orientation relative to five-membered ring (the torsion angle N(1)–C(2)–C(3)–O(3) is -93.7(7)°). It is rotated slightly rotated towards the plane of the aromatic cycle (the torsion angle C(8)–C(7)–N(3)–O(5) is 143.3(7)°). The doublets of H(2) and H(3) in the C=O and C–H bonds are situated closely too. In the crystal molecules of the compound 2g linked by the intermolecular hydrogen bonds O(3)–H(3)...O(4)’ (1-x, -0.5+y, 1.5-z) (H...O 2.32 Å, C–H...O 102°) takes place. The nitro group is intramolecular hydrogen bond C(9)–H(9)...O(3) (H...O 2.12 Å, O–H...O 171°). The doublets of H(1) and H(2) in the aromatic ring are situated closely too. The doublet of H(3) and H(4) protons of furan ring are situated closely in the same field.

The protonation of 4-HO-group with the further elimination of water yields “benzyl” cation A, which forms into 5-aryl-3-hydroxyhydantoin (4) by 1,2-shift and proton elimination from 4-HO-group. But the formation of destabilized cation B from 3,4,5-trihydroxy-5-(4-nitrophenyl)imidazolin-2-ones (2g and 3g) seems to be more hindered. It is possible that such a strong electron-donating substituent group in aryl’s fragment, as the nitro group makes this transformation impossible.

4-Nitrophenylglyoxal reacts with 2-methylfuran only in acetic acid (r.t.) selectively yielding 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone (5e) (Scheme 6). Into inert solvents, such as CH₂Cl₂ or THF, we couldn’t obtain the compound 5e.

Scheme 6. Synthesis of 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone (5e)

In this case, any α→β benzoin isomerization hasn’t occurred. The structure of the compound 5e is consistent with data of 1H and 13C NMR and MS spectra. In 1H NMR spectrum of the compound 5e, the doublets of H(3) and H(4) protons of furan ring are situated closely in the same field. That is a test on α-benzoin’s structure. The doublets of C(2,6)H and C(3,5)H protons are situated closely too. In mass spectrum cation C [M+H-H₂O]+ (m/z 244), 4-nitrobenzoyl cation D (m/z 150) and “benzyl” furyl cation E (m/z 111) dominate (Scheme 7), which is typical for α-benzoin’s.

Contrary to the other arylglyoxals, in acetic acid at the room temperature 4-nitrophenylglyoxal reacts with N-hydroxyurea giving only the mixture of 3,4,5-trihydroxymimidazolin-2-ones (2g and 3g in molar ratio near 3:1) (r.t., 25h). 3-Hydroxy-5-(4-nitrophenyl)hydantoin (4g) didn’t form. But, earlier we supposed that the presence of acid (acetic acid or excess of N-hydroxyurea) make to be easy the transformation 5-aryl-3,4,5-trihydroxymimidazolin-2-ones (2 and 3) into 5-aryl-3-hydroxyhydantoins (4 and 7) (Scheme 5).

The protonation of 4-HO-group with the further elimination of molecule of water yields “benzyl” cation A, which transforms into 5-aryl-3-hydroxyhydantoin (4) by 1,2-shift and proton elimination from 4-HO-group. But the formation of destabilized cation B from 3,4,5-trihydroxy-5-(4-nitrophenyl)imidazolin-2-ones (2g and 3g) seems to be more hindered.

It is possible that such a strong electron-donating substitute group in aryl’s fragment, as the nitro group makes this transformation impossible.

4-Nitrophenylglyoxal reacts with 2-methylfuran only in acetic acid (r.t.) selectively yielding 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone (5e) (Scheme 6). Into inert solvents, such as CH₂Cl₂ or THF, we couldn’t obtain the compound 5e.

Scheme 6. Synthesis of 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone (5e)

In this case, any α→β benzoin isomerization hasn’t occurred. The structure of the compound 5e is consistent with data of 1H and 13C NMR and MS spectra. In 1H NMR spectrum of the compound 5e, the doublets of H(3) and H(4) protons of furan ring are situated closely in the same field. That is a test on α-benzoin’s structure. The doublets of C(2,6)H and C(3,5)H protons are situated closely too. In mass spectrum cation C [M+H-H₂O]+ (m/z 244), 4-nitrobenzoyl cation D (m/z 150) and “benzyl” furyl cation E (m/z 111) dominate (Scheme 7), which is typical for α-benzoin’s.

Contrary to the other arylglyoxals, in acetic acid at the room temperature 4-nitrophenylglyoxal reacts with N-hydroxyurea giving only the mixture of 3,4,5-trihydroxymimidazolin-2-ones (2g and 3g in molar ratio near 3:1) (r.t., 25h). 3-Hydroxy-5-(4-nitrophenyl)hydantoin (4g) didn’t form. But, earlier we supposed that the presence of acid (acetic acid or excess of N-hydroxyurea) make to be easy the transformation 5-aryl-3,4,5-trihydroxymimidazolin-2-ones (2 and 3) into 5-aryl-3-hydroxyhydantoins (4 and 7) (Scheme 5).

The protonation of 4-HO-group with the further elimination of molecule of water yields “benzyl” cation A, which transforms into 5-aryl-3-hydroxyhydantoin (4) by 1,2-shift and proton elimination from 4-HO-group. But the formation of destabilized cation B from 3,4,5-trihydroxy-5-(4-nitrophenyl)imidazolin-2-ones (2g and 3g) seems to be more hindered.

It is possible that such a strong electron-donating substitute group in aryl’s fragment, as the nitro group makes this transformation impossible.

4-Nitrophenylglyoxal reacts with 2-methylfuran only in acetic acid (r.t.) selectively yielding 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone (5e) (Scheme 6). Into inert solvents, such as CH₂Cl₂ or THF, we couldn’t obtain the compound 5e.

Scheme 6. Synthesis of 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone (5e)

Scheme 7. Fragmentation pattern of 2-hydroxy-2-(5-methylfuran-2-yl)-1-(4-nitrophenyl)ethanone (5e) (FAB)

Conclusions

The reaction of 4-nitrophenylglyoxal with N-hydroxyurea leads to the mixture of diastereomers of 3,4,5-trihydroxy-5-(4-nitrophenyl)imidazolin-2-one. The diastereomer with cis-orientation of OH-groups dominates. Its structure has been investigated by X-ray structural analysis.
The reaction of 4-nitrophenylglyoxal with 2-methylfuran is also possible, but only in the special conditions – in the acetic acid medium at the room temperature. The product of this reaction is α-benzoin, which did not isomerize into β-benzoin in these conditions last time.
