**Abstract**—HTTP Vulnerability is an important security threat in this era. Currently attacks like SQL and DOS attacks are utmost common threats originate in the web applications. Mostly web application security vulnerabilities are SQL injection in which statements from SQL are reformed by attackers which is accomplished by applications over the web and presented to the server containing database. This type of attack is happening direct to lack of parameters used in SQL used and validation of input. Different type of latest web application attacks are SQLi, cross site scripting, session management and broker authentication , security misconfiguration ,insecure direct object references, , CCRF are identified in this paper. System developed attack identification and detection of SQL injection attack by using cloud service provider. This paper shows infrastructure on the cloud with virtual machine. Security groups are created to monitor the network traffic as inbound and outbound. Some test cases are performed to identify and detect such a type of attacks. Different pattern of attacks are considered. Risk and challenges of SQL injection attacks are mentioned.SQL injection attack model performance is shown in the system.

**Index Terms**— HTTP Vulnerability, Web Application Attacks, Cloud Service Provider, Virtual Machine, SQLi performance.

## I. INTRODUCTION

Nowadays every third person is connected to internet. This exposure to internet brings a threat to his/her data security. Attackers are active more than earlier as people are not too much IT literate or even in some cases systems are not full proof. So, there is a need to consider web application security. Obviously if there is concept of web application security, it is related to cloud security. In this paper challenges of cloud security are studied according to threats, needs and current survey of cloud security. Cloud security research areas are considered like virtualization, cloud security dimensions, data security, data separation, encryption, denial of service, DDoS Attacks etc. Characteristics of cloud security are achieved in terms of data security, data integrity, data confidentiality, scalability, better performance, and resource pooling. Many users upload their data on cloud or on different websites, so data security is important and is to be achieved. By using security rules there is no scope for malicious modification and integrity is maintained. Data confidentiality is information centric for secure transfer of files. If cloud service provider is used, resources can be scale up or scale down as per application need. Obviously by using cloud and any CSP system can achieve better performance. Resource pooling is like reserving resources for the application and after usage resources are released. In this paper detection of malicious traffic is done with the help of protocols and

vulnerability ontology. Hence identification of HTTP vulnerability attacks like DDoS attacks are detected. Finally with the help of local host and cloud time and space complexity is achieved.

### II. RELATED WORK

Most of the papers have presented identification and detection of web application attacks by using SQL injection attack. Ref. [1] shown prevention, detection and demerits of SQL injection attacks by using cloud computing service provider's firewall. Cloud database contents are authorized through several checkpoints. The security of the database is maintained by these checkpoints. These checkpoints can be harmed by the SQLIA at any of the service (EaaS, DaaS, SaaS, IaaS, PaaS,). Methods used provides resource sharing over wide access of network between different users, this will result availability of resources as per need to provide data security. Ref. [2] showed the performance of the system by tokenizing the user input query ex. double dashes, white space, sharp sign and so on. Every single string token was identified through the content of lexicon predefined ( ) most of reserved words commands and some logical operators. Injected commands like after concept drop, delete execute, sleep, shut down, union, or if. System performed few queries of sql injection on query statements vulnerable like 10 tested queries among them 3 are normal and 7 are injected. This system is applied for effective avoidance from various queries(malicious) for insertions. Ref. [3], performed attack detection method of the SQL injection by deleting the SQL query parameter values is examined and findings are shown. Extra research is essential for accurate SQL injection attacks detection . These methods are used from detecting and checking originality. System combines dynamic as well static analysis. At dynamic Parameter values are removed and associated by analyzing with SQL query. After removal of the parameter values comparison is done for both.query is normal when both values are same, if not same then the query is not normal. Ref. [4] detected attacks of vulnerability triggered because of performed input by different users those are not validated properly crosswise the application of web , proposed application done identification of attacks but not focused-on protection of data from threats and attacks in web applications. Different types of attacks are studied like XSS mechanism of analyzer detection, validation of protocol for attacks, SQL injection, buffer overflow. Authors also analyzed malicious attacks by suggesting mitigation and prevention of attacks. Ref. [5] gives standard injection attack of SQL and technologies related to prevention,, which are introduced input validation are not done on all parameters by providing methods. It shows characteristics of prevention methods and SQL injection attack. This type of attack can be presented by validation of input parameter methods like type safe SQL. Defense model is proved to inhibit injection attacks of SQL by assessing the size of input ,queries intended with the actual queries. The method can be used for defending application of web.

### III. METHODS

System developed by using both ways local host and cloud. Software's used are putty, winSCP, fiddler tool and protégé tool. Putty is used to connect remote machine with local machine by using some commands. These commands used to check status of remote machine, to get IP address of remote machine. WinSCP i.e., windows secure copy protocol is Microsoft clients to transfer files securely between local machine and remote machine. Fiddler tool is open source used to capture network traffic of local machine and remote machine .It is associated with web application firewall WAF. AWS services used from elastic computing cloud EC2 like IAM, MFA, Modsecurity. With a bunch of service of EC2 it is easy to create infrastructure needed to write rules for security. Ref. [6] used virtual machine network traffic can be analyzed. Identity access management is used for roles of users. Multifactor authentication code is attached to particular security group. Modsecurity is nothing but web application firewall. It is used with by default rules or users can create their own rules. As per ref. [7], once environment setup is ready on virtual machine, firstly testing is done on local machine. It uses MVC architecture of java i.e., model view and control. To give protection to the system functions are used to identify and detect attacks. Ref. [8] shown attacks like ICMP, HTTP, TCP, UDP and

*Section A-Research paper*

private port attacks. Ontology rules are written for inbound, outbound, JSON and policy rules. Inbound is for incoming traffic from anywhere i.e. source. Outgoing traffic is for outgoing to anywhere i.e., destination. Java script object notation is used to store key value pairs in the form of pointer values. Ref. [9], [10] Policy rules are based on automated rules like tailor rule. Overall rules are written by creating security groups.

*A. SQL-Injection Attack (Injection Flaws)*

HTTP Vulnerability: SQL injection attacks and DOS attacks are two furthestmost significant security threats initiated in applications over the web. one of the web application security vulnerabilities are SQL injection in this statements of SQL are changed by attackers which is accomplished by application over the web and presented to the server containing databases. This type of attack is initiated due for lack of input validation and parameters of SQL . Different type of latest web application attacks is SQLi , broker authentication and session management, cross site scripting insecure direct object references, security misconfiguration, CSRF [13][14].

*B. Attack Patterns Example*

These are classified into attack types and attack payload string. Tautology  
'OR' '1'='1' Line Comment ') or '1'=1-- Bypassing login screens Admin '—

*C. Risk & Challenges of SQL Injection Attack*

To prevent insecure deserialization vulnerabilities, developer should,

- Sanitize serialized object data as user input like untrusted via filtering or validation.
- Implement integrity check like digital signatures or any serialized object. This will inhibit tampering.
- Finally by isolating run code that deserializes in a low privileged environment [15][16].

*D. SQLi Detection and Prevention Techniques Detection Mechanism:*

➤ Detection Mechanism:

- Injection through user input.
- Vulnerability scanning and security testing.
- Web application firewalls.
- Secure development training.

➤ Prevention Mechanism:

- Train and maintain awareness.
- Don't trust any user input.
- Adapt to the latest technologies.
- Scan regularly.
- Implement WAF in front of the application.
- Integrate WAF in web server as well use cloud based WAF.

*E. HTTP Response Splitting Attack*

Attack happens when:

- Entry of data to a web application through source which is untrusted, highly often an HTTP request.
- The data is entered in an HTTP response header transmitted to a user of web without being validated for malicious characters.
- In the proposed system implementation is not done for detection of HTTP response splitting attack.
- Design patterns to create domain ontology are semantic rules.

- Described ontology pattern for SQLi attack is reusable so it can also be applied for HTTP response splitting attack.

#### IV. RESULTS

##### a. Environment setup

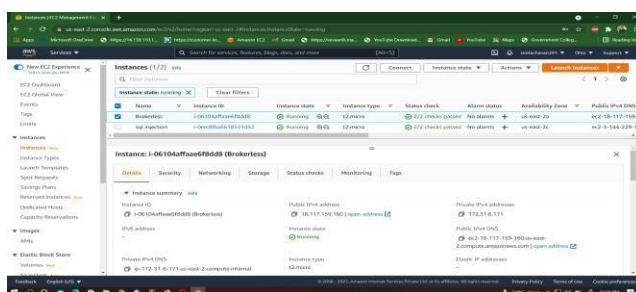

Figure.1. AWS (EC2) Instance Creation Steps and Configuration

As per above fig.1 virtual machine is created i.e. instance on AWS. It will give instance id, type. In the diagram instance state is shown as running. Instance type is t2 micro. Status check is 2/2 that all services related to this virtual machine working properly. If user wants to set alarm for notification it can be possible. Availability zones are shown with its public IPv4 DNS address [17][18][19].

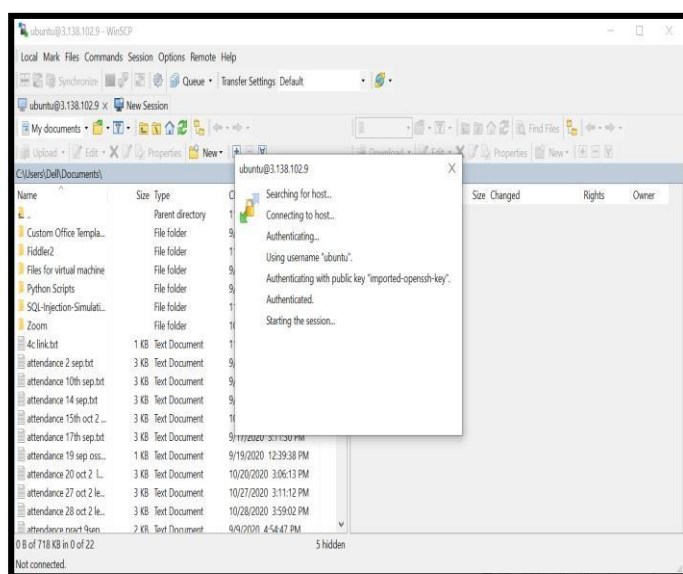

Figure.2-a. Local host Connectivity

Fig.2 (a) shows local host connectivity by using windows secure copy protocol. With WinSCP Putty option local machine is connected to virtual machine. Session will start by entering few of the commands and it will give IP address of connected remote machine [20][21].

Figure.2-b. Local host connectivity

As per Fig.2 (b) system can analyze configurations of virtual machine. It uses fiddler tool as debugger to capture network traffic. Hence it will show header status either empty or ok. It is possible with IP addresses [22][23].

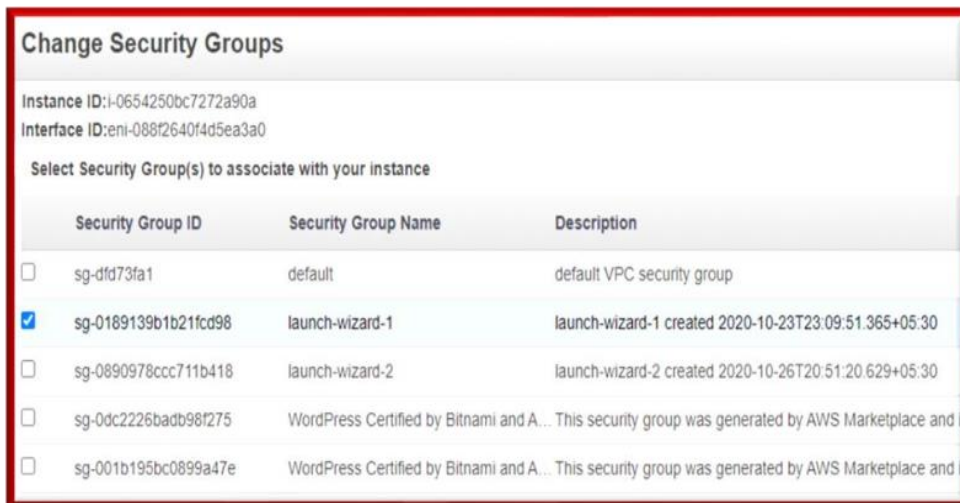

Figure.3. Security group creation

Ref. [11], above diagram fig.3 shows created security groups for virtual machine users. There are two ways to create security group. One is by default from EC2 service. Second by creating own security group. As per Eur. Chem. Bull. 2023, 12(Special Issue 7), 401-416

*Section A-Research paper*

diagram shown instance id security group is attached with security group ID, security group name and its overall description[24][25].

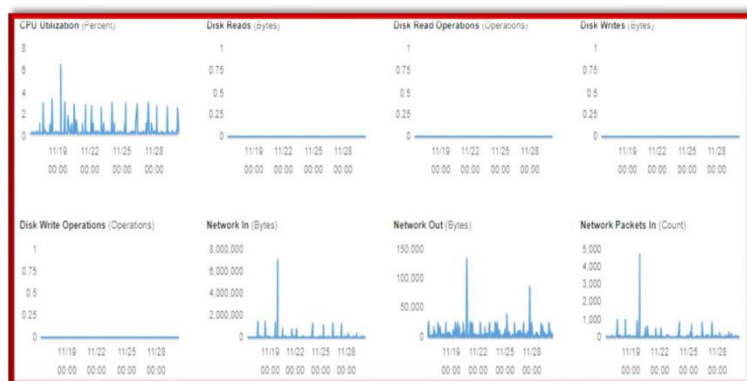

Figure.4. Performance of Virtual Machine

Virtual machine performance can be captured from instance information and its ID as shown in Fig.4.as per the resources used performance is calculated. Figure shows Total CPU utilization, network in bytes, network out bytes as well as total of network packets count [24][25][26].

Table 1: Test cases

Test No.	Test Data	Result	Test Status	Remark
1	Username and Blank Password xie' or '1'--'	Account Balance: 50000	Pass	Without Protection
2	Username and Password is same 1' or '1'=1 1' or '1'=1	User ID or Password is invalid	Fail	With Protection
3	Common user login Username xie Password darren1	Account Balance: 50000	Pass	Without Protection

Ref. [12] as per table 1, above test cases is performed to validate attacks. These cases show identification and detection of SQL injection attacks. Different Methods are used to provide protection. Test performed on intentionally vulnerable web applications example sites; we got SQL injection scanner report as start time, finish time, scan duration and test count. We will also get vulnerable parameter, risk description. Hence performing one test will take 41 seconds [27][28].

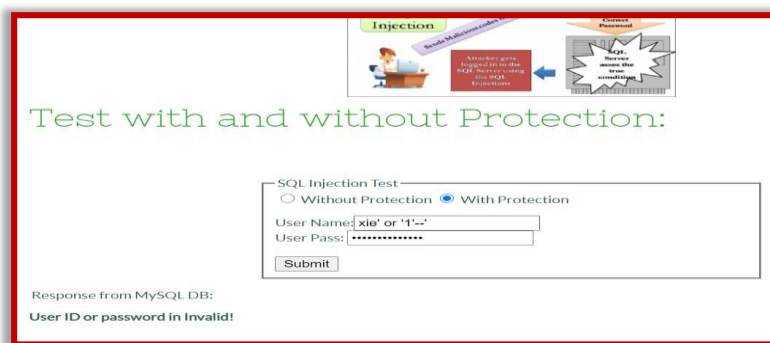

Figure.5. Test Case Execution of SQL Injection Attack

Ref [13] Figure 5 shows result of SQL injection attack. If user will select with protection that means rules are written and if user will select without protection it means without rules. If protection is provided so there is no possibility of attacks and vice versa [29][30].

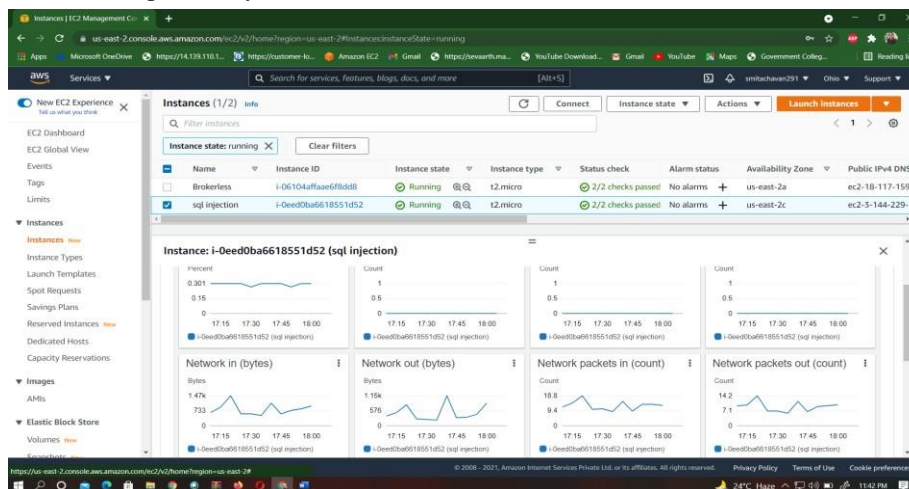

Figure.6.Instance performance by using AWS

Instance performance is observed as per incoming and outgoing traffic to that instance. It is shown in figure 6.

<a href="#">/user_profile.php</a>	pass	POST	<a href="http://vulnapp.example.com/user_profile.php">http://vulnapp.example.com/user_profile.php</a> <b>POST Data:</b> pass=ZAP' OR '1'='1' --

### Risk description:

SQL injection may be possible.

### Recommendation:

Do not trust client-side input, still there is client-side validation in place. typically, type checks all data on the server side. If the application uses JDBC, use prepared statement or callable statement, with parameters passed by '?' This does not eliminate SQL injection, but minimizes its impact. Grant the minimum database access that is necessary for the application.

Scantype: Light Authentication: False

## CONCLUSION

The system uses a new approach to ensure authentication and confidentiality. Types of HTTP vulnerability attacks are identified. Simulation of SQL injection attack and identity-based encryption successfully deployed on virtual machine using AWS EC2 services. Hence observed that by using cloud services, deployment of application takes less time with good storage capacity. System gives optimized results on cloud as compared to local machines. System proposed a new attack detection method for web application attacks with HTTP structure. This proposed system is used for sensitive website like banking. In future, this type of application can be used in organization or any industry to detect and prevent web-based attacks. Instead of SQL injection attack other vulnerabilities can be considered to identify and detect attacks.
