Abstract

Organometallic drugs of Ca(II), Fe(III), Co(II), Ni(II), Cu(II), Zn(II), Ag(I), Cd(II), Hg(II) and Pb (II) with N-(4-aminophenyl)-2-hydroxybenzamide ligand have much potential as therapeutic and cytotoxic agents against Prostatic carcinoma cell line (PC-3). Specific examples involving the design of metal complexes as anticancer and antimicrobial agents are discussed. These complexes have been synthesized and characterized using transmission electron microscope (TEM), Scanning electron microscope with EDEX, (mass, IR, UV-VIS and ESR) spectroscopy, XRD, as well as magnetic moments, conductance, elemental and thermal analyses. Molar conductance in DMF solution indicates that, the complexes are non-electrolytes. The ESR spectra of solid Cu (II) complex **(8)** showed isotropic type indicating an octahedral geometry with covalent bond character. X-ray Diffraction Spectroscopy XRD has been done. The XRD reveal that cu(II) complex **(6)** , Zn (II) complex **(11)** and Ag (I) complex **(12)** these complexes have the average crystallite sizes of 27.1,22.6 and 7.11 nm respectively. It was suggested that the complexes were Nano crystalline. Fluorescence spectroscopy had been done for HL **(1)**, CU (II) complex **(6)**, Zn (II) complex **(11)** and Ag (I) complex **(12)**. Cytotoxic evolution against Prostatic carcinoma cell line of the ligand and its complexes have been carried out. Ligand **(1)** and its complexes showed enhanced activity in comparison to the standard drug (Cisplatin) was applied with IC$_{50}$ = *8.51-401.18 µg/ml* range. Zn(II) complex **(11)** was the most potent cytotoxic agent against prostatic carcinoma with IC$_{50}$ = *8.51 µg/ml which candidates as anticancer agent. Also Antimicrobial activity had been carried out.*

Keywords: Amide ligand, complexes, magnetism, ESR, XRD, cytotoxicity, prostatic carcinoma.

Introduction

The American Cancer Society estimates that there will be 248,530 new cases of prostate cancer in 2021 and more than 3.1 million prostate cancer survivors in the United States [1]. The American Cancer Society also estimates that prostate cancer will be the second leading cause of cancer-related death in US men after lung cancer in 2021 [2]. Furthermore, rates of

3495

Eur. Chem. Bull. 2023,12(12), 3495-3531

prostate cancer are higher in men of African descent compared with men of European descent [3]. Germ line testing (genetic testing for genes linked with hereditary cancer risk has emerged as integral to prostate cancer precision treatment in the metastatic setting, is increasingly informing screening strategies, and provides hereditary cancer information for men and their families [4]. In recent years, there has been an exponential rise in understanding the role of genetic mutations in prostate cancer predisposition and the development of new precision therapies [5, 6]. Many genes are now incorporated into the guidelines for genetic testing to assess the risk of developing prostate cancer and offer guidance for targeted therapeutics [7]. In May 2020, the US Food and Drug Administration (FDA) approved 2 poly(adenosine diphosphate [ADP]-ribose) polymerase (PARP) inhibitors for the treatment of men with metastatic, castration-resistant prostate cancer (mCRPC) based on improved clinical responses [8]. Metallo-drugs (organometallic reagents) are pharmacologically active compounds having metal atoms, which are essential for their microbial and antitumor activities, such as anticancer [9]. Metallo-drugs offer many features over purely organic compounds due to specific characteristics of coordination compounds. Their bioactivity is affected by the type of central atom, its coordination and oxidation number, type and number of the ligands, coordination geometry and charge of the complex [10]. In recent years, the coordinated Chemistry of diamines have attracted the attention of researchers due to their unique capability of constructing complicated organic molecules using centres of metal as intermediates. For example, N-phenyl-ortho-phenylenediamine coordinated to platinum or nickel atoms transforms into imidazophenazine derivatives [11]. The coexistence of hydrolizable ester group (-COO-) and amide group (-NHCO-), which are capable of establishing strong intermolecular hydrogen bond interactions, becomes fundamental to obtaining a suite of materials with tailored properties. Specifically, different polyester amides have been developed for biomedical applications such as drug delivery systems [12]. Literature survey reveals that nitrogen - and sulfur-containing compounds showed very good bioactivity, being potentially active against cancer as well as viral and fungal diseases [13]. The amide moiety has attracted further interest because it is widespread in natural and synthetic drugs and shows lower toxicity [14]. Bioactivity of amides can also be achieved by constructing the amide with hydroxypentanedioate [15]. In a variety of disciplines, such as environmental, inorganic, analytical chemistry, and bio-medical science, the fluorescence spectroscopy has developed into a common sensor that detects a highly useful substance. They have offered highly sensitive, selective, and accurate online and cost-effective detection of harmful ions of heavy metal, enzymes, and anions [16]. The purpose of the research is to prepare and spectroscopically characterized new metal complexes of amide ligand and also to develop an analytical method for quickly and economically detecting

3496

Eur. Chem. Bull. 2023,12(12), 3495-3531

amide ligand. The using of spectro fluorimetric approach which has excellent simplicity, sensitivity, and selectivity. Prostate cancer affects men of all racial and ethnic groups and leads to higher rates of mortality in those belonging to a lower socioeconomic status due to late detection of the disease. There is growing evidence that suggests the contribution of an individual's genetic profile to prostate cancer [17]. Currently used prostate cancer treatments have serious adverse effects; therefore, new research is focusing on alternative treatment options such as the use of genetic biomarkers for targeted gene therapy, nanotechnology for controlled targeted treatment, and further exploring medicinal plants for new anticancer agents. Herein, we reported synthesis and characterization of new metallo-therapeutic candidates derived from the novel ligand 1 N-(4-aminophenyl)-2-hydroxybenzamide ligand. The cytotoxic activity of synthesized compounds has been also investigated.
Materials and methods

All the reagents employed for the preparation of the ligand and its complexes were synthetic grade and used without further purification. TLC is used to confirm the purity of the compounds. C, H, N and Cl analyses were determined at the Analytical Unit of Cairo University, Egypt. A standard gravimetric method was used to determine metal ions [18]. All metal complexes were dried under vacuum over P_4O_{10}. The IR spectra were measured as KBr pellets using a Perkin-Elmer 683 spectrophotometer (4000-400 cm-1). Electronic spectra (qualitative) were recorded on a Perkin-Elmer 550 spectrophotometer. The conductance(10^{-3}M) of the complexes in DMF were measured at 25°C with a Bibby conduct meter type MCl. ^{1}H-NMR spectra of the ligand and its Cd(II) complex were obtained with Perkin-Elmer R32-90-MHz spectrophotometer using TMS as internal standard. Mass spectra were recorded using JEULJMS-AX-500 mass spectrometer provided with data sys-tem. SEM using Edex and transmission electron microscope (TEM) for the prepared complexes were recorded at electron microscope unit faculty of Science Alexandria University. The thermal analyses (DTA and TGA) were carried out in air on a Shimadzu DT-30 thermal analyzer from 27 to 800°C at a heating rate of 10°C per minute. Magnetic susceptibilities were measured at 25°C by the Gouy method using mercuric tetrathiocyanatocobalt(II) as the magnetic susceptibility standard. Diamagnetic corrections were estimated from Pascal's constant [19]. The magnetic moments were calculated from the equation: The ESR spectra of solid complexes at room temperature were recorded using a varian E-109 spectrophotometer; DPPH was used as a standard material. The TLC of all compounds confirmed their purity. The fluorescence spectroscopy has developed into a common sensor that detects a highly useful substance. They have offered highly sensitive, selective, and accurate online and cost-effective detection of harmful ions of heavy metal, enzymes, and anions [20]. The purpose of the research is to

3497

Eur. Chem. Bull. 2023,12(12), 3495-3531

prepare and spectroscopically characterized new metal complexes of amide ligand and also to develop an analytical method for quickly and economically detecting amide ligand. The Using spectrofluorimetric approach which has excellent simplicity, sensitivity, and selectivity. per minute. All fluorescence measurements were acquired by an FS5 spectrofluorometer (Edinburgh, UK) with a 150 W xenon lamp source for excitation. Also, with 1-cm quartz cell and connected to Fluoracle® software. The slit widths were set to 2 nm and scanning speed 1000 nm/min.

Experimental

HL**;(1)** was prepared as shown in scheme 1 and then was stirred for 30 minutes. After cooling, the solvent was removed under reduced pressure to give crude product which was crystallized in ethanol to yield pure ligand (**1**). Ligand (1): Yield 83 %; m.p. 296; color is Black; Anal. Calcd. (%) for C13H14N2O3 (FW = 246.26): C, 63.40; H, 5.73; N, 11.38; Found (%) C, 63.64; H, 5.64; N, 11.54; IR (KBr, cm^{-1}), 3450 υ(OH), 3123 υ(NH), 3423 υ(NH$_2$), 1627 υ(C=O), 1512, 760 υ(C=C)Ar.

Synthesis of metal complexes (2)-(15): The metal complexes (**2**) and (**3**) were prepared by refluxing with string a suitable amount (1 mmol) of a hot ethanolic solution of the following metal salts and (CaCl$_2$.2H$_2$O),(FeCl$_3$.3H$_2$O), (Co(CH$_3$COO)$_2$.4H$_2$O), (Ni(CH$_3$COO)$_2$.4H$_2$O), (Cu(CH$_3$COO)$_2$.H$_2$O), (CuCl$_2$.2H$_2$O), (CuSO$_4$.5H$_2$O), (Zn(CH$_3$COO)$_2$.2H$_2$O), (AgNO3), (Cd(CH$_3$COO)$_2$.2H$_2$O), (HgCl$_2$), (Pb(CH$_3$COO)$_2$.2H$_2$O) to prepare complexes (**2-4),(6)** and (**12**) with molar ratio (1M:1L) respectively. On the other hand ethanolic solution of metal salts was added to Ligand solution with molar ratio (1M:2L) to afford metal complexes (**4-5), (8-11),(13)** and (**15**). From another way solvation of metal salts with ethanol and then added the ligand solution with molar ratio (2M:1L) to obtain metal complex (**7**).The refluxing times varied from 2 to 4 hours according to the depending to nature of metal ion. 3 mL of diethyl amine were added to the reaction mixture in order to initiate precipitation of complex. The precipitates, were filtered off, washed with ethanol then by diethyl ether and dried in vacuum desiccators over P$_4$O$_{10}$.

Biological activity

Cytotoxic activity:

Mammalian cell lines: PC-3 (prostate carcinoma) were obtained from VACSERA Tissue Culture Unit.

Chemicals used: Dimethyl sulfoxide (DMSO), crystal violet and trypan blue dye were purchased from Sigma (St. Louis, Mo., USA).

Fetal Bovine serum, DMEM, RPMI-1640, HEPES buffer solution, L-glutamine, gentamycin and 0.25% Trypsin-EDTA were purchased from Lonza.

Crystal violet stain (1%): It composed of 0.5% (w/v) crystal violet and 50% methanol then made up to volume with ddH_2O and filtered through a Whatmann No.1 filter paper.

Cell line Propagation:

The cells were propagated in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% heat-inactivated fetal bovine serum, 1% L-glutamine, HEPES buffer and 50µg/ml gentamycin. All cells were maintained at 37ºC in a humidified atmosphere with 5% CO_2 and were subcultured two times a week.

Cytotoxicity evaluation using viability assay: For cytotoxicity assay, the cells were seeded in 96-well plate at a cell concentration of 1×10^4 cells per well in 100µl of growth medium. Fresh medium containing different concentrations of the test sample was added after 24 h of seeding. Serial two-fold dilutions of the tested chemical compound were added to confluent cell monolayers dispensed into 96-well, flat-bottomed microtiter plates (Falcon, NJ, USA) using a multichannel pipette. The microtiter plates were incubated at 37ºC in a humidified incubator with 5% CO_2 for a period of 24 h. Three wells were used for each concentration of the test sample. Control cells were incubated without test sample and with or without DMSO. The little percentage of DMSO present in the wells (maximal 0.1%) was found not to affect the experiment. After incubation of the cells for at 37°C, for 24 h, the viable cells yield was determined by a colorimetric method. In brief, after the end of the incubation period, media were aspirated and the crystal violet solution (1%) was added to each well for at least 30 minutes. The stain was removed and the plates were rinsed using tap water until all excess stain is removed. Glacial acetic acid (30%) was then added to all wells and mixed thoroughly, and then the absorbance of the plates were measured after gently shaken on Microplate reader (TECAN, Inc.), using a test wavelength of 490 nm. All results were corrected for background

3503

Eur. Chem. Bull. 2023,12(12), 3495-3531

absorbance detected in wells without added stain. Treated samples were compared with the cell control in the absence of the tested compounds. All experiments were carried out in triplicate. The cell cytotoxic effect of each tested compound was calculated. The optical density was measured with the microplate reader (SunRise, TECAN, Inc, USA) to determine the number of viable cells and the percentage of viability was calculated as [(ODt/ODc)]x100% where ODt is the mean optical density of wells treated with the tested sample and ODc is the mean optical density of untreated cells. The relation between surviving cells and drug concentration is plotted to get the survival curve of each tumor cell line after treatment with the specified compound. The 50% inhibitory concentration (IC$_{50}$), the concentration required to cause toxic effects in 50% of intact cells, was estimated from graphic plots of the dose response curve for each conc. using Graphpad Prism software (San Diego, CA. USA) [21].

^{1}H-NMR spectra of the ligand (1) and complexes (11, 13 and 15):

The ^{1}H-NMR spectra of ligand (1) and complex (11) in deutrated DMSO showed peaks consistent with the proposed structure.The ^{1}H-NMR spectrum of the ligand showed chemical shift observed as singlet at 10.53 ppm which was assigned to proton of hydroxyl group. The chemical shift which appeared at 8.3 ppm was attributed to the proton of NH attached to (CH- of aromatic ring); (CO-NH-Ar-). However, The NH$_2$ proton of aromatic was observed as a singlet at 6.3 ppm. A set of signals appeared as multiples in the 6.6-6.9 ppm range, corresponding to protons of aromatic ring [22].By comparison the ^{1}HNMR of the ligand and the spectrum of the complex (11); signal was observed as a singlet at 10.4 ppm characteristic to the O*H* group indicating that the ligand found in the protonated form. In addition, there is a significant downfield shift of the NH attached to (CH- of aromatic ring); (CO-NH-Ar-) proton signal relative to the free ligand clarified that the metal ions are coordinated to the amide nitrogen atom. This shift may be due to the formation of a coordination bond (NHC═O-M)) [23] (Chart (1))
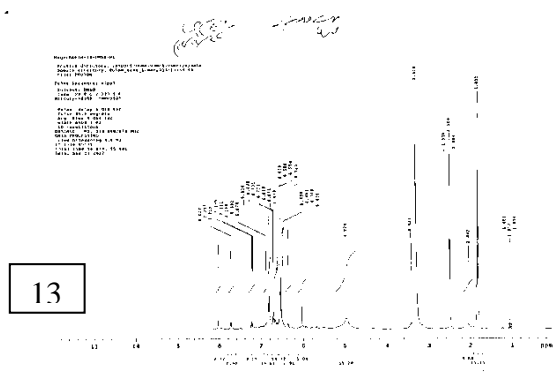

3505

Eur. Chem. Bull. 2023,12(12), 3495-3531

Chart (1): ^{1}H-NMR spectra of the ligand (1) and complexes (11, 13 and 15)

IR spectra:

The mode of bonding between the ligand and the metal ion revealed by comparing the IR spectra of the ligand (1) and its metal complexes (2)-(15). The ligand showed bands in the 3600-3340 and 3330-2650 cm^{-1} ranges, commensurate the presence of two types of intra- and intermolecular hydrogen bonds of OH and NH groups with carbonyl group [24]. Thus, the higher frequency band was associated with a weaker hydrogen bond. The medium band appeared at 3123 cm^{-1} was assigned to υ (NH) group [25]. The υ (NH) group in the complexes appeared nearly at the same region of the free ligand indicating that, the NH group is not involved in the coordination to the metal ion [26]. However, the characteristic bands of υ (NH$_2$) and υ (C=O) amide were observed at (3423 and 3390) and 1627 and cm^{-1} respectively. Strong band appeared at 3450-1215 cm^{-1} was attributed to the υ (C-OH) vibration. The bands appeared at 1512, 1460, 760 and 710 cm^{-1} range, were assigned to υ (Ar) vibration [27]. By comparing the IR spectra of the complexes (2)-(15) with that of the free ligand. It was found that, The υ (NH$_2$) group in the complexes appeared nearly at the same region of the free ligand indicating that, the NH$_2$ group is not involved in the coordination to the metal ion [28]. The υ (C=O) amide complexes appeared at 1630-1610 cm^{-1} range indicating that, the υ (C=O) amide group was involved in the coordination to the metal ion [29]. In acetate complexes, (5-8), (11),(13) and (15) in these complexes bands were observed in the 1576-1340 cm^{-1} range suggesting the coordination of acetate group in these complexes as a monodentate, fashion [30]. The sulphato complex (10) showed bands at 1178, 1115, 1021 and 652 cm^{-1} respectively assigned to monodentate sulphate group [31]. Complexes (12) show bands at 1380,1250 and 850 cm^{-1} range these have been assigned to the nitrato group. Complexes (11)-(12) show bands in the 590-535cm^{-1} was assigned to υ (M-N) [32]. Complexes (2-15) showed bands in the 668-603cm^{-1} range due to υ (M- O) [33] . Complexes (2),(3),(9) and (14) showed bands in the 482-418cm^{-1} range this has been assigned to the υ (M-Cl).

Mass spectra

The mass spectra of (1) and its, Ca(II) complex (2) Ag(I) complex (12) and Hg(II) complex (14) confirmed their proposed formulation. The spectrum of (1) reveals the molecular ion peak (m/z) at 246 amu consistent with the molecular weight of the ligand. Furthermore, the fragments observed at (m/z) = 49,08, 79.90, 137, 146.20,182.49,233.02and246.40amu correspond to C_2H_4, C_5H_3O, $C_7H_7NO_2$, $C_9H_{10}NO_2$, $C_9H_{12}NO_3$, $C_{12}H_{13}N_2O_3$ and, $C_{13}H_{14}N_2O_3$ moieties respectively. Complex (2) shows fragments (m/z) at 64.43, 117.80, 147.35, 191.94, 266.47, 311.53and 375.65amu due to C_5H_3, C_8H_4O, $C_9H_6O_2$, $C_9H_{10}CaO_2$, $C_{11}H_{12}CaClNO_2$, $C_{12}H_{15}CaClN_2O_3$ and $C_{13}H_{16}CaCl_2N_2O_4$

3507

moieties respectively. The fragments observed (m⁄z) at 77.23, 90.12, 178.23, 329.09, 406.31 and 435.29 amu for complex (12) were assigned to C_3H_6, C_7H_7, $C_9H_6NO_3$, $C_{10}H_6 AgNO_5$, $C_{11}H_{11} AgN_3O_7$, and $C_{13}H_{16}AgN_3O_7$ moieties, whereas the spectrum of Hg(II) complex (14) showed molecular ion peak at 554.15 assigned to the molecular weight of the complex and also showed fragments at 76.75, 175.33, 408.26, 438.39, 460.20, 448, 524.41 and 554.15 which were assigned to C_6H_3, $C_{10}H_3 ClO$, $C_{10}H_3ClHgO_3$, $C_{11}H_5ClHgO_4$, $C_{11} H_{13} ClH_9NO_4$, $C_{12}H_{14} Cl_2HgNO_5$ and $C_{13}H_{18} Cl_2 HgN_2O_5$. moieties respectively.

Magnetic moments:

The magnetic moments of the metal complexes (4-13) and (15) at room temperatures were shown in (Table 1). Co (II) complex (4) showed value in the 4.75B.M, range corresponding to one unpaired electron in an octahedral structure [34]. Ni (II) complex (**5**) showed value in the 3.12 B.M, range corresponding to one unpaired electron in an octahedral structure, Cu (II) complexes (6-10) showed values in the 1.17, 1.65, 1.69 and 1.70B.M, range corresponding to one unpaired electron in an octahedral structure. Zn (II) complex (11), Ag (I) complex (12), Cd (II) complex (13) and Pb (II) complex (15) showed diamagnetic property [35].

Electronic spectra:

The electronic spectral data for the ligand (1) and its metal complexes in DMF solution are summarized in (Table 3). Ligand (1) in DMF solution shows two bands at 320 nm (ε =7.72 x 10^{-3} mol^{-1} cm^{-1}) and 295 nm (ε = 7.12x 10^{-3} mol^{-1} cm^{-1}) which may be assigned to n→π* and π→π* transitions of the immine and aromatic ring respectively. Copper(II) complexes (6)-(10) show bands in the 295-275 and 310-305 nm ranges , these bands are due to intraligand transitions, however, the bands appear in the 495-455, 580-500 and 620-600 nm ranges, are assigned to O→Cu, charge transfer, $^2B^1$→^2E and $^2B1$→$^2B2$ transitions, indicating a distorted tetragonal octahedral structure. However, cobalt(II) complex (4) shows bands at 285, 300, 400, 440, 510, 585, 620 and 623 nm, the first two bands are within the ligand and the other bands are assigned to $^4T1g(F)$→$^4T2g(P)(v3)$, $^4T1g(F)$→$^4A2g(v2)$ and $^4T1g(F)$ $^4T2g(F)(v1)$ transitions respectively. Zinc (II) complexes (11) shows bands due to intra ligand transitions. However, nickel(II) complexes (**5**) shows bands at 280, 295, 305, 307, 450, 656, 620 and 765 nm, the first three bands are within the ligand and the other bands are attributable to O→Ni charge transfer, $^3A2g(F)$→$^3T1g(P)(v3)$, $^3A2g(F)$→$^3T1g(F)(v2)$ and $^3A2g(F)$→$^3T2g(F)(v1)$ transitions respectively, indicating an octahedral Ni(II) geometry. The $v2/v1$ ratio for (**5**) is 1.23 which are less than the usual range of 1.5-1.75, indicating a distorted octahedral Ni (II) complex [36].

Table (3). The electronic absorption spectral bands (nm) and magnetic moments (B.M) for the ligands (1),(2) and their metal complexes.

No.	Ligand/Complexes	λ_{max} (nm)	μ_{eff} (BM)	ν_2/ν_1

Thermal analysis (DTA and TGA):

Since the IR spectra indicated the presence of water molecules, thermal analyses (DTA and TGA) were carried out to certain their nature [37]. The thermal curves in the temperature 27-800°C range for complexes (2),(3),(5),(6),(8),(9),(11),(12),(13),(14) and (15) were thermally stable up to 45 °C. Broken of hydrogen bondings occured as endothermic peak within the temperature 45-50 °C range as shown in (Table 3). Dehydration was characterized by endothermic peaks observed within the temperature 65-80°C range, corresponding to the loss of hydrated water molecules as in complexes (2),(3),(5),(6),(8),(9),(11-15) The elimination of coordinated water molecules occured in the 140-145°C range accompanied by endothermic peaks [38]. The TGA and DTA thermogram of Ca(II) complex (2) showed that,

3509

the complex decomposed in six steps. The first occurred at 45°C with no weight loss as endothermic peak, was due to break of hydrogen bondings. The second step occur at 75°C with 8.41 % weight loss (Calc. 8.61%) as endothermic peak which could be due to the elimination of hydrated water molecule. The decomposition step which occurred at 145°C with 8.19 % weight loss(Calc. 8.61%) could be due to the elimination of two coordinated H_2O molecules. The TGA curve displayed another thermal decomposition at 265-280°C range with 16.91% weight loss (Calc. 17.07%), which could be due to the loss of coordinated chloride group. The complex showed an exothermic peak observed at 301°C was due its melting point. Finally, exothermic peaks appeared at 445, 490, 570 and 610 °C corresponding to oxidative thermal decomposition which proceeded slowly with leaving CaO with 13.74% weight loss (Calc. 13.65%) [39]. The TGA and DTA thermogram of Fe(III) complex (**3**) showed endothermic peak observed at 70 with 7.96% weight loss (Calc. 8.13%) which could be due to the elimination of hydrated water molecule. The decomposition process which occurred at 143°C with 4.31% weight loss (Calc. 4.06%) could be due to the elimination of coordinated H2O molecule. The endothermic peak observed at 270°C with 16.96% weight loss (Calc. 16.01%), could be due to the elimination of two chloride groups. Another endothermic peak observed at 309°C with no weight loss may be due to its melting point. Finally, the complex showed exothermic peaks observed at 470, 510, 580 and 600°C with 35.99% weight loss (Calc. 36.08%) corresponding to oxidative thermal decomposition which proceeded slowly with final residue, assigned to Fe_2O_3 . The TGA and DTA thermogram of Ni(II) complex (**5**) showed endothermic peak observed at 48°C, was due to break of hydrogen bondings. Another endothermic peak appeared at 65°C, with 3.12% weight loss (Calc.2.77 %), was due to loss of one hydrated water molecule. The endothermic peak observed at 140°C with 18.31% weight loss (Calc. 18.15%), could be due to the elimination of two coordinated acetate groups. Another exothermic peak observed at 302 with no weight loss may be due to its Melting point. Finally oxidative thermal decomposition occured at 425, 485, 530 and 605°C with exothermic peaks, leaving NiO with 11.41% weight loss (Calc. 11.37%) [40]. The TGA and DTA thermogram of Cu (II) complex (**6**) decomposed in five steps. The first occurred at 50°C with no weight loss as endothermic peak, was due to break of hydrogen bondings. The second step occured at 75°C with 7.91 % weight loss (Calc. 7.07%) as endothermic peak which could be due to the elimination of two hydrated water molecule. Another endothermic peak observed at 142°C with 6.88% weight loss (Calc. 7.07%) was assigned to the loss of two coordinated water molecule.. At 312°C, endothermic peak appeared which was due to melting point. Oxidative thermal decomposition occured at 475,530,595 and 610 °C with exothermic peaks, leaving CuO with 11.98% weight loss (Calc. 12.36%) [41]. The TGA and DTA thermo gram of Cu (II) complex (**8**) decomposed in five

3510

Eur. Chem. Bull. 2023,12(12), 3495-3531

steps. The first occurred at 45°C with no weight loss as endothermic peak, may be due to break of hydrogen bonding. The second step occurred at 70°C with 2.72% weight loss (Calc. 2.74%) as endothermic peak which could be due to the elimination of one hydrated water molecules. Another endothermic peak observed at 265,270°C with 17.36% weight loss (Calc. 18.00%) was assigned to the loss of two Acetate groups. Another endothermic peak observed at with 315°C with no weight loss was due to melting point. Oxidative thermal decomposition occured at 425,490,540 and 600 °C with exothermic peaks, leaving CuO with 11.91% weight loss (Calc. 12.04%) [42]. The TGA and DTA thermogram of Cu(II) complex (**9**) decomposed in five steps. The first occurred at 49°C with no weight loss as endothermic peak, may be due to break of hydrogen bondings. The second step occured at 80°C with 8.18% weight loss (Calc. 8.41%) as endothermic peak which could be due to the elimination of two hydrated water molecule. Another endothermic peak observed at 140°C with 11.81% weight loss (Calc. 11.02%) was assigned to the loss of two chloride groups.. At 325°C, endothermic peak appeared which was due to melting point. Oxidative thermal decomposition occured at 440,495,540, 605 and, 640 °C with exothermic peaks, leaving CuO with 12.91% weight loss (Calc. 12.27%) [43]. The TGA and DTA thermogram of Zn(II) complex (**11**) showed endothermic peak at 48°C, due to break of hydrogen bonding. Another endothermic peak observed at 65°C with 2.33% weight loss (Calc. 2.74%) as endothermic peak which could be due to the elimination of hydrated water molecule. Another endothermic peak appeared at 285,300°C, with 20.12% weight loss (Calc. 20.88%), was due to loss of two acetate groups. Another endothermic peak observed at 333°C with no weight loss may be due to its melting point. Finally oxidative thermal decomposition occured in the 425, 490, 515 and 580 and °C with exothermic peaks, leaving ZnO with 12.80% weight loss (Calc. 12.11%) [44]. The TGA and DTA thermogram of Ag(I) complex (**12**) showed endothermic peak at 48°C, due to break of hydrogen bondings. Another endothermic peak observed at 70°C with 8.81% weight loss (Calc. 8.31%) as endothermic peak which could be due to the elimination of two hydrated water molecule. Another endothermic peak appeared at 285, 300°C, with 14.59% weight loss (Calc. 14.31%), was due to loss of nitrate group. Another endothermic peak observed at 320°C with no with no weight loss may be due to its melting point. Finally oxidative thermal decomposition occured in the 350, 400, 455 and 580 and °C with exothermic peaks, leaving AgO with 28.54% weight loss (Calc. 28.38%) [45]. The TGA and DTA thermo gram of Cd(II) complex (**13**) showed that, the complex decomposed in six steps. The first occurred at 45°C with no weight loss as endothermic peak, may be due to break of hydrogen bonding. The second step occured at 70°C with 4.07 % weight loss (Calc. 4.97%) as endothermic peak which could be due to the elimination of two hydrated water molecules. The decomposition step which occurred at 150°C with 16.99% weight loss (Calc. 16.29%) could be due to the

3511

Eur. Chem. Bull. 2023,12(12), 3495-3531

elimination of two acetate groups. The complex showed an endothermic peak observed at 315°C was due its melting point. Finally, exothermic peaks appeared at 425, 480, 540 and 580 °C respectively corresponding to oxidative thermal decomposition which proceeded slowly with leaving CdO with 34.16% weight loss (Calc. 34.34%) . The TGA and DTA thermogram of Hg(II) complex (**14**) decomposed in six steps. The first occurred at 49°C with no weight loss as endothermic peak, may be due to break of hydrogen bondings. The second step occured at 80°C with 3.63% weight loss (Calc. 3.25%) as endothermic peak which could be due to the elimination of one hydrated water molecule. Another endothermic peak observed at 144°C with 6.36% weight loss (Calc. 6.50%) was assigned to the loss of two coordinated water groups.. At 325°C, endothermic peak appeared which was due to melting point. Oxidative thermal decomposition occured at 440,495,540, and 605, °C with exothermic peaks, leaving HgO with 35.89% weight loss (Calc. 36.45%) . The TGA and DTA thermogram of Pb(II) complex (**15**) decomposed in five steps. The first occurred at 49°C with no weight loss as endothermic peak, may be due to break of hydrogen bondings. The second step occured at 80°C with 4.22% weight loss (Calc. 4.74%) as endothermic peak which could be due to the elimination of two hydrated water molecule. Another endothermic peak observed at 270,285°C with 15.1% weight loss (Calc. 15.54%) was assigned to the loss of two acetate groups.. At 325°C, endothermic peak appeared which was due to melting point. Oxidative thermal decomposition occurred at 440,490,560, and 605, °C with exothermic peaks, leaving PbO with 29.31% weight loss (Calc. 29.40%).

Electron spin resonance (ESR): The ESR spectral data for complexes (**4-8**) are presented in (Table 3). The spectra of Cu(II) complexes (**6-8**) are characteristic of species d^9 configuration having axial type of a $d(x_2-y_2)$ ground state which is the most common for copper(II) complexes [46]. The complexes showed $g_\parallel > g\perp > 2.0023$, indicating octahedral geometry around copper (II) ion [47]. The g-values are related by the expression $G = (g_\parallel-2)/(g\perp -2)$[48], where (G) exchange coupling interaction parameter (G). If G<4.0, a significant exchange coupling is present, whereas if G value > 4.0, local tetragonal axes are aligned parallel or only slightly misaligned. Complexes (**3**), (**4**) and (**5**) showed 3.14, 3.50 and 3.80 values indicating spin-exchange interactions took place between copper (II) ions. This phenomena is further confirmed by the magnetic moments values (1.43 and 1.69 B.M.). On the other hand, the $g_\parallel/A_\parallel$ value is also considered as a diagnostic term for stereochemistry [49]. The $g_\parallel/A_\parallel$ values for the copper complexes are 170.77, 170.00 and 168.5 cm^{-1} which lie just within the range expected for the tetragonal distorted octahedral copper(II)complexes (Table2). The g-value of the Cu(II) complexes with a ^{2}B1g ground state ($g_\parallel > g\perp$) may be expressed by[50].

$$g_\parallel = 2.002 - (8K^2_\parallel\lambda°/\Delta Exy) \tag{1}$$

$$g\perp = 2.002 - (2K^2\perp\lambda°/\Delta Exz) \tag{2}$$

3513

Where $k_\parallel$ and $k_\perp$ are the parallel and perpendicular components respectively of the orbital reduction factor (K), λ° is the spin-orbit coupling constant for the free copper, ΔExy and ΔExz are the electron transition energies of $^2B1g\rightarrow^2B2g$ and $^2B1g\rightarrow^2Eg$. From the above relations, the orbital reduction factors

($K_\parallel$, $K_\perp$, K), which are measure terms for covalence [51], can be calculated. For an ionic environment, K=1; while for a covalent environment, K<1. The lower the value of K, the greater is the covalency.

$$K^2{}_\perp = (g_\perp - 2.002) \Delta Exz / 2\lambda^o \tag{3}$$

$$K^2{}_\parallel = (g_\parallel - 2.002) \Delta Exy / 8\lambda^o \tag{4}$$

$$K^2 = (K2_\parallel + 2K^2{}_\perp)/3 \tag{5}$$

K values (Table 4), for the copper (II) complexes (**6**), (**7**) and (**8**) are indicating covalent bond character [52]. Kivelson and Neiman noted that, for ionic environment $g_\parallel \geq 2.3$ and for a covalent environment $g_\parallel < 2.3$ [53]. Theoretical work by Smith seems to confirm this view. The g-values reported here (Table 4) showed considerable covalent bond character. Also, the in-plane σ-covalence parameter, α^2 (Cu) was calculated by

$$\alpha^2 (Cu) = (A_\parallel/0.036) + (g_\parallel - 2.002) + 3/7(g - 2.002) + 0.04 \tag{6}$$

The calculated values (Table 4) suggested a covalent bonding [53]. The in-plane and out of-plane π-bonding coefficients $\beta1^2$ and β^2 respectively, are dependent upon the values of ΔExy and ΔExz in the following equations [54].

$$\alpha^2\beta^2 = (g_\perp - 2.002) \Delta Exy / 2\lambda o \tag{7}$$

$$\alpha^2\beta1^2 = (g_\parallel - 2.002) \Delta Exz / 8\lambda o \tag{8}$$

In this work, the complexes (**6**), (**7**) and (**8**) showed $\beta1^2$ values 2.84, 2.71 and 2.41 indicating a moderate degree of covalence in the in-plane π-bonding [55]. β^2 value for complexes (**6**), (**7**) and (**8**) showed 2.76, 2.54 and 2.23 indicating ionic character of the out-of-plane, [55]. It is possible to calculate approximate orbital populations for d orbitals [56] by

$$A_\parallel = A_{iso} - 2B[1 \pm (7/4) \Delta g_\parallel] \quad \Delta g_\parallel = g_\parallel - ge \tag{9}$$

$$\alpha p, d^2 = 2B / 2B^\circ \tag{10}$$

Where A° and $2B^\circ$ is the calculated dipolar coupling for unit occupancy of d orbital respectively. When the data were analyzed, the components of the [57]. Cu hyperfine coupling were considered with all the sign combinations. The only physically meaningful results are found when $A_\parallel$ and $A_\perp$ were negative. The resulting isotropic coupling constant was negative and the parallel component of the dipolar coupling 2B are negative (-196.4, -183.03 and -156.00 G). These results can only occur for an orbital involving the dx2-y2 atomic orbital on copper. The value for 2B is quite normal for copper (Il) complexes [58]. Complexes (**4**) and (**5**) showed isotropic spectra with g_{iso}= 2.03 and 2.02.

X-ray Diffraction Spectroscopy XRD pattern:

Powder X-ray Diffraction Spectroscopy XRD pattern of the Cu (II) complex **(6)**, Zn(II) complex **(11)** and Ag(I) complex **(12)** bearing CH3COO− were recorded in the range (2θ = 0–80) is shown in (Figure 8). The pattern of the metal complexes was studied to further obtain evidence about the structure of the metal complexes at wavelength 1.5406 ´Å. The XRD pattern of the Cu(II) complexes shows well defined crystalline peaks indicating that the Cu(II) ,Zn(II) and Ag(I)-Schiff base complexes were in crystalline phase. The average crystallite size of the complexes dXRD was estimated from XRD patterns by Scherer's formula: d_{XRD} = 0.9λ/β (cosθ) where 'λ' is the wavelength, 'β' is the full width at half maxima and 'θ' is the diffraction angle. The XRD reveal that [(HL)Cu(OAc)$_2$.(H$_2$O)$_2$].2H$_2$O, [(HL)$_2$Zn(OAc)$_2$]. H$_2$O and [(HL)AgNO$_3$].2 H$_2$O complexes have the average crystallite sizes of 27.10, 22.60 and 7.11 nm respectively. It suggests the complexes are nanocrystalline [59].

X-ray Diffraction Spectroscopy (XRD)

Fig. 8: X-ray Diffraction Spectroscopy XRD pattern of the Cu(II) complex (6):[A], Zn(II) complex (11):[B]

Scanning and transmission electron microscopy (SEM and TEM):

The SEM images revealed that the surface of compounds are uniformly covered by the Ligand (1) and Zn (II) complex (11) . The layers were amorphous and crystaline structures appeared. The dimention of these crystalites ranged from 7.41 to 16.71 μm Fig.4 [60].

The TEM images reveal that the average diameter of particles size of the ligand (1) and Zn (II) complex (11) were determined to be 18.53-43.75 nm and 18.31-32.77 nm respectively. Ligand and Zn (II) complex (11) were present in Nano size particle i.e., their particles present in a diameter between 1 and 100 nm in size. Ligand and complex (11) show sign with ratio that exhibit new or enhanced size-dependent properties compared with larger particles of the same material with many advantages such as: Increased bioavailability, dose proportionality, decreased toxicity, smaller dosage form (i.e., smaller tablet), stable dosage forms of drugs which are either unstable or have unacceptably low bioavailability in non-Nano particulate dosage forms, increased active agent surface area results in a faster dissolution of the active agent in an aqueous environment, such as the human body, faster dissolution generally equates with greater

3516

bioavailability, smaller drug doses, less toxicity and reduction in fed/fasted variability [61].

**Fig. 9. TEM images for HL (1) and ZN(II) Complex (11)**

Fig.10. SEM images for HL (1); a,b and Zn(II) complex (11); c,d with different magnification

Fluorescence spectroscopy

The emission spectra of the ligand HL(1), Cu(II) complex **(6)**, Zn(II) complex (11) and Ag(I) complex (12) were recorded in DMF and were shown in Fig. 11. [62]. After an excitation

3517

wavelength of 290 nm, the Cu (II) metal complex **(6)** showed an emission wavelength of 390 nm, and discovered to be red shifted. Furthermore, the red shift of the emission wavelength in the case of Cu (II) may be caused by the primary amino group. Additionally, the conjugation of the ligand and metal complex resulted in an increase in fluorescence intensity. The copper; Cu (II) metal complex has fluorescent in nature, as seen by the fluorescence emission spectra Fig. 11 (A) & (B).

Chemotherapeutic Studies: Cytotoxic evolution against prostatic carcinoma cell line of the ligand and its complexes have been carried out. Ligand (1) and its complexes showed enhanced activity in comparison to the standard drug (Cisplatin) was applied with $IC_{50} = 8.51\text{-}401.18 \ \mu g/ml$ range. Zn (II) complex **(11)** was the most potent cytotoxic agent against prostatic carcinoma with $IC_{50} = 8.51 \ \mu g/ml$ which candidates as anticancer agent.

Antimicrobial Activity

In vitro biological screening tests of the ligand and metal complexes **(1), (6), (11), (12)** and **(13)** carried out as antibacterial and antifungal activity and presented in table 5 and figure 12. The antibacterial activity was tested against two bacterial strains; Gram-positive and Gram-negative strains. The results compared with standard drug (Ampicllin (Gram positive) and Gentamicin (Gram negative). The data indicated that, complexes were active against bacteria. The results showed that the cytotoxic effect against Gram positive and Gram negative strains is Cd (II) complex **(13)** was high effect, for *E.coli* the order of cytotoxic effect was standard > complex **(11)** = complex **(13)** and others were zero effect. Complex **(1)** , **(6)** and **(12)** had no effect against Bacillus subtilis, Staphylococcus aurous, *E.coli, candida albicans* and Pseudomonas aeruginosa .Cd(II) complex showed wide range of bactericidal activities against the gram positive and gram negative bacteria. Further, the Cd (II) complex **(13)** was more active than the free ligand, which indicates that, metalation increases antimicrobial activity.

Conclusion

Metalloorganic complexes of Ca(II), Fe(III), Co(II), Ni(II), Cu(II), Zn(II), Ag(I), Cd(II), Hg(II) and Pb(II) with N-(4-aminophenyl)-2-hydroxybenzamide amide ligand have much potential as therapeutic and cytotoxic agents against Prostatic carcinoma cell line (PC-3). Specific examples involving the design of metal complexes as anticancer and antimicrobial agents have been synthesized and characterized by transmission electron microscope (TEM), Scanning electron microscope with EDEX, (mass, IR, UV-VIS and ESR) spectroscopy, XRD, as well as magnetic moments, conductance, elemental and thermal analyses. Molar conductance in DMF solution indicates that, the complexes are non-electrolytes. The ESR spectra of solid Cu (II) complex **(8)** showed isotropic type indicating an octahedral geometry with covalent bond character. X-ray Diffraction Spectroscopy XRD has been done. The XRD reveal that cu (II) complex **(6)**, Zn (II) complex **(11)** and Ag (I) complex **(12)** these complexes have the average crystallite sizes

3524

of 27.1,22.6 and 7.11 nm respectively. It was suggested that the complexes were nanocrystalline. Cytotoxic evolution against Prostatic carcinoma cell line of the ligand and its complexes has been carried out. Ligand (1) and its complexes showed enhanced activity in comparison to the standard drug (Cisplatin) was applied with $IC_{50} = 8.51\text{-}401.18 \ \mu g/ml$ range. Zn(II) complex **(11)** was the most potent cytotoxic agent against prostatic carcinoma with $IC_{50} = 8.51 \ \mu g/ml$ *which candidates as anticancer agent. Antimicrobial activity also, had been carried out.* These organometallic compounds candidates as ant prostatic cancer agents.
